SKF

SKF CONVEYOR PULLEY BEARING HOUSING FOR HIGH PERFORMANCE

Includes detailed assembly instructions and lubrication guidelines for SDVD series housings.

SKF Conveyor pulley bearing housings

Specifically designed and developed for conveyor pulleys in mining, minerals processing and bulk materials handling.

Split plummer block housings in small (500 series) and medium (3100 series) sizes, with shaft diameters up to 300 mm are commonly used in the general mining and mineral processing industries.

Application duties can vary from moderate to severe, with a high focus on contamination exclusion and greasing effectiveness. End users typically require a high level of standardization and interchangeabililty. High performance and reliable operation are also standard prerequisites. Spherical roller bearings with integral seals (SSRB) are commonly specified. Taconite housing seals are mandated almost exclusively.

For pulley designers and manufacturers, the objective is to have readily available, cost effective products with minimised overall width. This allows for pulley design optimization and cost benefits, along with ease of installation.

SKF SDVD 500 series and SDVD 3100 series housings, with SKF Explorer sealed spherical roller bearings, are a perfect choice for this industry segment. All housings are 4 bolt mount, spheroidal graphite (ductile) cast iron material, with bolt-on closed end covers.

SDVD housings are designed specifically for the demands of the mining sector and similar industries. The width of the housings and seals has been minimised, allowing them to be fitted to existing pulleys designed for the same bearing series. Housing seals are a bolt-on (unsplit) TKV Taconite style seal with axial labyrinth and V-ring.

For larger pulleys (shaft diameters above 300 mm), SDJD 3100 series housings with TKV Taconite seals (bolt on style) are the appropriate choice.

Interface dimensions (mounting bolt pattern, shaft centre height, base footprint) are fully compatible with the (F)SNL(D) housings and the generic FSSN(D) 5 series and SD(D) 31 series found in various markets.

Design features and manufacturing specifications for SDVD housing assemblies are tailored to provide the optimum balance of:
- User-friendliness
- High performance
- Cost of ownership

Market

Application duties in mining and mineral processing industries vary from moderate to severe.

- High focus on contamination exclusion and greasing effectiveness

End users require:

- High performance
- Reliable operation
- Ease of maintenance
- Cost-effective products which enable
  - Standardization
  - Interchangeability
  - Low cost of ownership

Pulley designers and manufacturers require:

- Readily available products
- Cost-effective products
- Simplicity of installation
- Minimized overall housing assembly width
  - Optimization of pulley design
  - Cost reduction benefits

Industry

SKF SDVD housings are designed specifically for the demands of the mining sector and similar industries.

Housing Assemblies

- Have minimised width
- Can be fitted to any exisiting pulleys using the same basic bearing series

Housings

- 4-bolt mount base
- Manufactured in spheroidal graphite cas iron for robustness
- Bolt-on end covers

Housing Seals

- Bolt-on (unspilt) TKV taconite style
- With axial labyrinth and V-ring

SKF SDVD Series Housings

- Incorporate SKF Explorer sealed spherical roller bearings (SSRB), the perfect choice for this industry segment
- Conventional unsealed spherical roller bearings are also fully compatible

OPTIMISED DESIGN

Benefits for conveyor pulley application

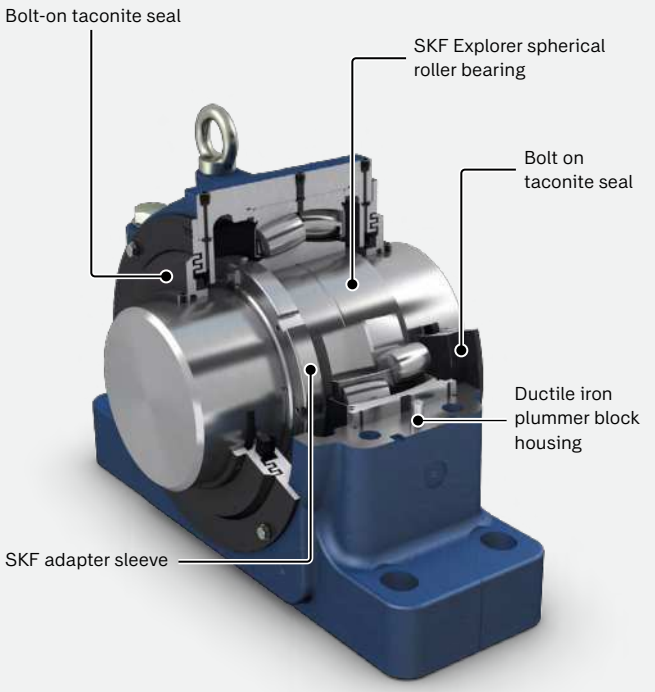
- Universally applicable due to minimised assembly width; SDVD housings can be retrofitted to all existing pulleys which use the same basic bearing housing size series
- Optimised design and reduced cost for new pulleys due to minimised assembly width
- Simple installation (initial assembly and in-situ rebuilds)
- Easy and accurate pulley alignment and in-situ maintenance; SDVD design facilitates bearing changes in-situ
- Delivers high performance, high reliability and can contribute to longer bearing service life

Table of contents

SDVD housing design features

- Non-symmetrical design: minimised width at inboard (pulley drum) side
- Seal carrier recessed into housing body: minimised assembly width
- Bearing seat form optimised for maximum service life and minimum vibration levels
- Seal carrier mounting opening diameter maximised:
  - Minimum pulley lift required to change bearings in-situ, if required
  - SKF Drive-up Method applicable for bearing inside the housing (valid for SDVD 31 series)
  - Allows accurate and reliable mounting if changing bearing in-situ
- Centre line markings on base to assist pulley installation and alignment in both planes
- Spot faced positions for vibration sensors (horizontal, vertical and axial positions)
- Base and cap with unique match mark to eliminate risk of mixing components

Plummer block housing with through shaft



Plummer block housing with shaft ending in housing

* Patent pending

TKV sealing

For bearing arrangements which operate under very arduous conditions such as those encountered in mining, taconite seals are recommended, as direct grease supply enhances the sealing effect and extends the service life of the seals.

The TKV taconite seal is based on the same well-proven concept as the SKF TK heavy duty taconite seals, but is designed specifically to be part of the SDVD housing system, creating a narrow assembly.

The labyrinth accommodates axial movement of the shaft relative to the housing and angular misalignment of up to approximately 0.5°.

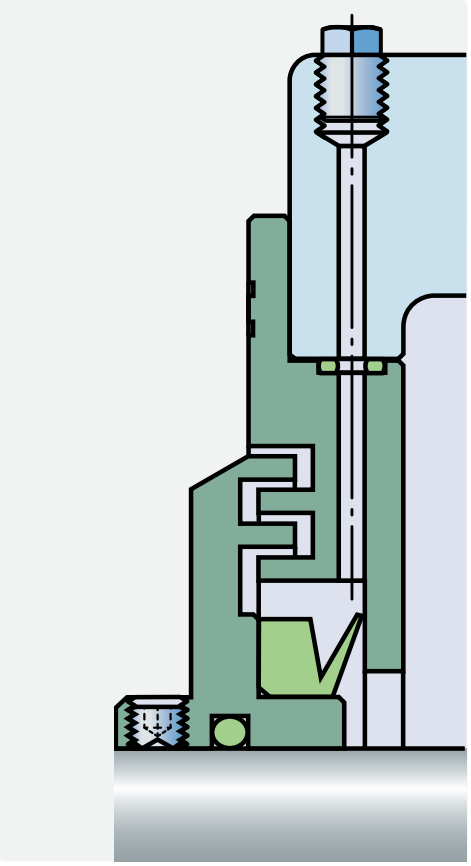
Grease is supplied to the labyrinths via pre-tapped entry points on each side of the housing cap.

A V-ring seal mounted on the rotating labyrinth ring runs against the non-rotating part of the seal, which is bolted to the side of the housing. The V-ring assists the grease purge passage out through the labyrinth, as well as acting as another barrier preventing contamination from penetrating to the bearing.

The permissible operating temperature range for the nitrile V-ring is between –40 and +100 °C *(–40 to +210 °F)*. This can be improved by substituting a V-ring manufactured from an alternative material, e.g. FKM (Viton).

TKV taconite seals are supplied individually. For housings used on through shafts, it is necessary to order two seals.

The seal is identified by the designation prefix TKV followed by the size identification, e.g. TKV 517 or TKV 34.



TKV Taconite seal design features

- Axial labyrinth configuration
  - Flinger effect from rotating labyrinth art
  - No shaft damage due to wear as the V-ring lip is not in contact with the shaft
  - High quality V-ring runs on unsplit counter face
  - Easy and precise installation (labyrinth gap setting)
  - Positive location on shaft (set screws)
  - Static sealing on shaft (O-ring)
- Labyrinth clearances optimized for:
  - Sealing performance
  - Misalignment capability
  - Axial displacement capability
- Grease inlet on housing cap
  - Robust attachment
  - No access limitations
  - Improved operator safety
  - Assembly width minimised
- Protective shroud
  - Optional extra for extremely contaminated areas or frequent wash-down

SDVD housing technical details

Load-carrying capability

Split plummer block housings are intended primarily for loads acting perpendicularly to the support surface or within a moderate angle. If the housing is fully supported along its base and the applied forces act purely perpendicularly, the load capacity is limited only by the bearing.

If loads act in other directions, or if the housing is not fully supported along its base, be sure that the load magnitude remains within limits for the housing, the cap bolts and the attachment bolts.

SDVD housings are suitable to accommodate load magnitudes typically applied to standard mining conveyor pulleys. In case of extreme loading conditions, please contact SKF for advice.

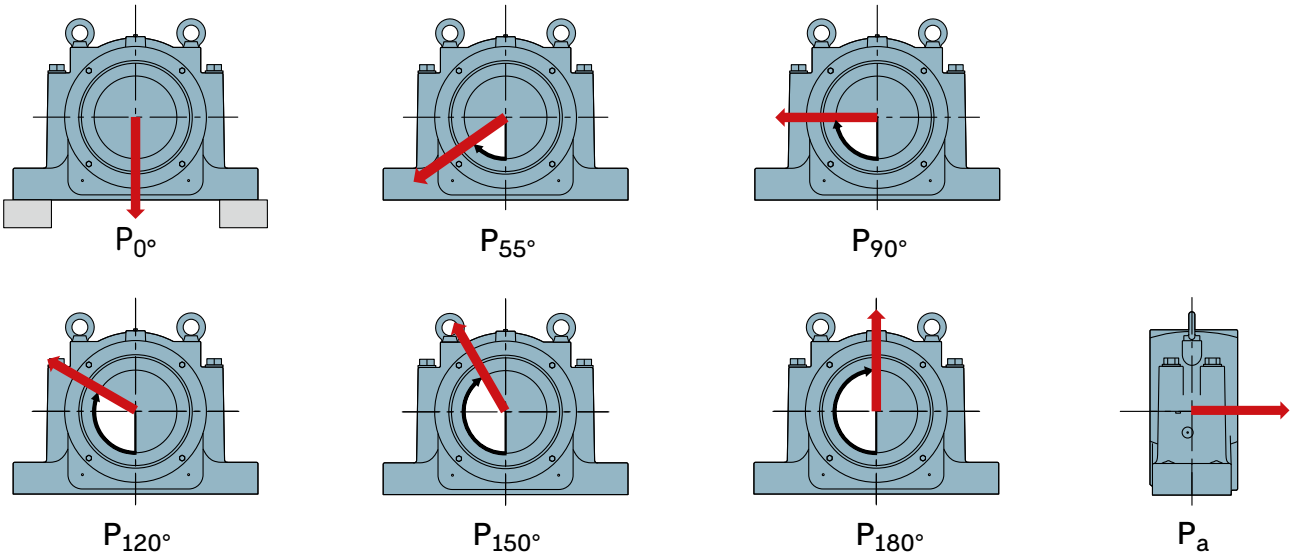
Additional housing support

When the housing is subjected to loads acting parallel to the support surface, i.e. when loads act at angles between 55° and 120°, or when the axial loads are greater than 5% of $P_{180°}$, the housing should be pinned to the support surface or should be provided with a stop to counter the lateral load. The dowel pins or stops should be sufficiently strong to accommodate the loads acting parallel to the support surface.

Load-carrying capabilities of the cap bolts

SDVD housings are supplied with cap bolts of ISO Class 8.8 or higher. When the cap bolts are tensioned according to specification **(→ table 2)**, the safe working loads for the housing can be fully exploited.

Load direction definitions



Safe loads

Safe loads can be used instead of breaking loads. Approximate safe loads are listed in table 1 on page 13. These guideline values have been established using accepted engineering practices, taking safety, ultimate tensile strength of the materials and working stresses into account. They reflect a safety factor of 5 against fracture, and a minimum factor of 2 against cap bolt yield.

Note: Images are for representation only and do not represent the actual housing profile.
Refer to table 1 for maximum recommended safe working loads in each direction.
Safe working loads have safety factor of ~5 against failure.

Recommended maximum safe working loads

Table 1

Housing	Safe loads

Note: Maximum recommended safe working loads have a safety factor of ~5 against failure.
These guideline values have been established using accepted engineering practices, and taking safety, ultimate tensile strength of the materials and working stresses into account.

Bolt tightening torque recommendations

In typical applications, the housing is attached to the support structure using ISO 4014 hex head bolts (ISO Class 8.8 or higher) and washers.

SKF SDVD housings can withstand loads resulting from tightening the attachment bolts to the torque values recommended by bolt manufacturers **(→ table 2)**. The torque values are valid for oiled, but otherwise untreated, thread surfaces.

SKF cannot guarantee that tightening bolts to the recommended value will provide sufficient anchoring in all circumstances. If necessary, dowels or stops should be provided to ensure sufficient support for expected loads.

Bolt torques can be increased for loads up through the cap, or for abnormal application load conditions.

Standard bolt torque recommendation for SDVD housings in typical conveyor duty

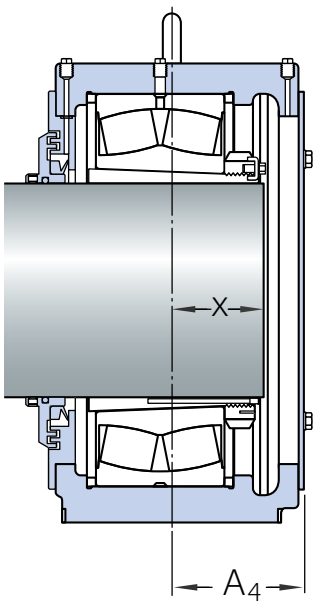
Housings for shaft ends



Housings mounted at the end of a shaft are typically fitted with a closed end cover.

The covers are bolted onto the side of the housing.
A flange sealant is recommended to be applied between these surfaces for improved contamination exclusion.

Details of the permissible length of the shaft end for housings for shaft ends can be found in table 5 for SDVD 500 series and table 4 for SDVD 3100 series.

The end covers are made from mild steel plate and are supplied with 4 screws & washers.

The standard end cover for SDVD housing is identified by the designation prefix ETV followed by a series of numbers representing OD/screw PCD/no. of screws.

For example, ETV 290/265/4 is suitable for the SDVD 3134 housing.

Locating rings

The width of the bearing seat in SDVD housings accommodates locating or non-locating bearing assemblies.

The locating bearing, which secures the shaft axially in both directions, must have locating rings installed in the housing at both sides of the bearing outer ring.

The non-locating bearing is left free to move axially in the housing to accommodate thermal expansion of the shaft.

Locating rings are identified by the designation prefix FRB followed by figures indicating the width/outside diameter in millimeters.

For example, FRB 10/280.

Recommended shaft length for end of shaft mounting for SDVD 3100 series housings — Table 4

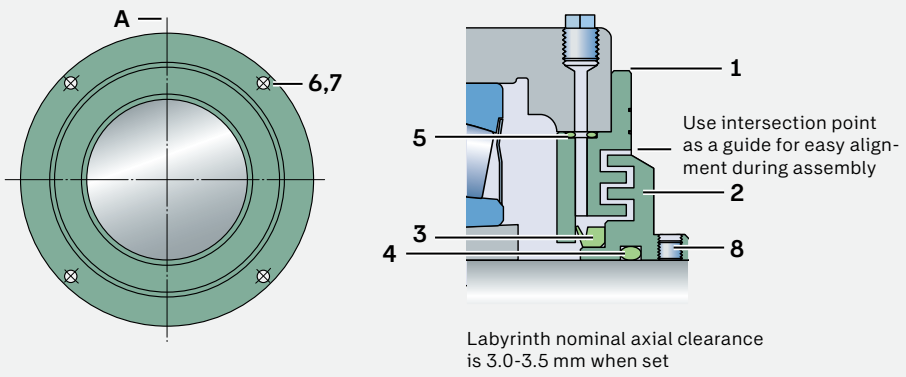
TKV seal arrangement details

Det	Qty	Description
8	3	Set screw-cup point
7	4	Plain washer
6	4	Hex head bolt
5	2	Quad ring
4	1	O-ring
3	1	V-ring
2	1	Labyrinth seal
1	1	Seal carrier



Labyrinth nominal axial clearance is 3.0-3.5 mm when set

SDVD detailed assembly instructions

Before beginning installation, ensure all components are in good condition and grease supply ducts in the housing cap and seal carriers (1) are clean and free from obstruction.

1. Assemble the inboard seal components onto the shaft.

a. Grease and fit the O-ring (4) and V-ring (3) onto the outboard labyrinth seal (2).

b. Slide the labyrinth seal (2) past its final position. NOTE: Do not tighten set screws (8) at this stage.

c. Slide the seal carrier (1) along the shaft into position.

2. Mount the bearing and adapter sleeve onto the shaft as per standard procedure (see skf.com/mount for further information).

Fill the bearing with grease (only for bearings without integral seals).

Lower the shaft, bearing and and seals into the housing base. Position the shaft system or housing axially so that the bearing is centered in the housing.

For locating bearing arrangements, place locating rings on both sides of the bearing.

Fill the housing cavity with grease. The correct amount can be found in table 6.

3. To assemble housings for through shaft with seals at both sides:

a. Move the outboard seal carrier (1) into position.

b. Grease & fit the O-ring (4) and V-ring (3) onto the outboard labyrinth seal (2).

c. Slide the outboard labyrinth seal along the shaft, but do not position it into its final location and do not tighten set screws.

4. Apply a thin bead of Loctite 510 along the housing base split line. Do not use an excessive amount to avoid seepage into the bearing seat.

Place the housing cap over the bearing onto the housing base, then tighten the cap bolts to the required torque values.

5. Grease and fit the rubber quad ring (5) into the recess in the seal carrier (1).

Apply a bead of Loctite 510 around the housing side faces, including around the seal carrier mounting surface.

6. Slide the seal carrier(s) into position and bolt them to the housing face(s) using 4 off M10 hex head screws (6) and washers (7).

NOTE: Ensure the quad rings (5) are positioned towards the top of the housing cap, so that the grease inlet ducts are aligned. Take care that Quad rings are not damaged or dislodged during insertion of the carriers into the housing body.

For shaft-end housings, attach the end cover to the outboard side face of the housing using 4 x M10 hex head screws (6) and washers (7). (Apply sealant to the mounting faces.)

Fill the labyrinths with grease and then position the labyrinth seals (2) using the corner of the chamfer on the labyrinth seal outer diameter to axially align it with the face of the seal carriers (1) and to provide the appropriate seal clearance. Axial clearance in the labyrinth = 3–3.5 mm nominal depending on size.

Tighten the 3 off set screws (8) in the labyrinth seal rings. Torque each screw to 8–15 Nm (depending on size).

7. Align the housing to within the misalignment tolerance (refer to page 21). Secure the hold down bolts to the recommended torque value.

Ensure appropriate grease fittings are installed at each of the 3 grease inlet ports on the housing cap.

Note that ports adjacent to closed-end covers should be plugged if a bearing with integral seals is used.

To ensure grease ports remain unobstructed, pump grease into the housing cap ports until it purges through the labyrinths. Do not inject grease into the bearing itself.

Align the housings in position of final installation.

SDVD housings with TKV seals are intended for grease lubrication. The lubricant should be selected based on the operating conditions of the bearing. For additional information about lubricant selection, refer to the product information available online at skf.com.

Initial grease fill

If no other requirements exist, the free space in the bearing itself should be completely filled with grease and the free space in the housing should be filled to between 20 to 80% of its volume depending on the specific application.

For highly contaminated environments and slow speeds, to ensure best protection against contaminants, use the SKF Three-barrier solution (with sealed spherical roller bearings). In that case, fill the housing to 70–80% of the free space.

In other applications with conventional (unsealed) bearings or frequent grease supply requirements, a 40% grease fill is recommended when bearings have to be relubricated from the side, while a 20% grease fill is recommended when bearings are relubricated via the outer ring.

For additional information, contact the SKF application engineering service.

Quantities for various housing grease fills are listed in table 6.

For the TKV seal initial grease fill, refer to tables in the appendix.

Relubrication

SDVD plummer block housings enable relubrication of the incorporated bearings and seals (fig. following page):

- SDVD housings are supplied with 3 holes in the cap drilled and tapped for 1/4″ BSP* grease fittings.
- The holes are fitted with steel plugs and optional grease nipples are provided loose.
- The central grease hole supplies the central lubrication groove of the bearing.
- 2 grease holes on each side of the bearing are positioned for seal purging.
- If a larger grease fitting or other equipment has to be used, adapters can be sourced separately.

Eye bolts

For SDVD housings in the size range 520-532, a single lifting eye bolt is provided, which can be fitted into the central relubrication threaded hole in the housing cap, if required.

During installation, after the housing cap has been positioned, the eye bolt should be removed and replaced with a grease nipple or fitting for a lubrication system.

Initial grease fill (cm^3 or grams)

Relubrication points for SDVD assemblies

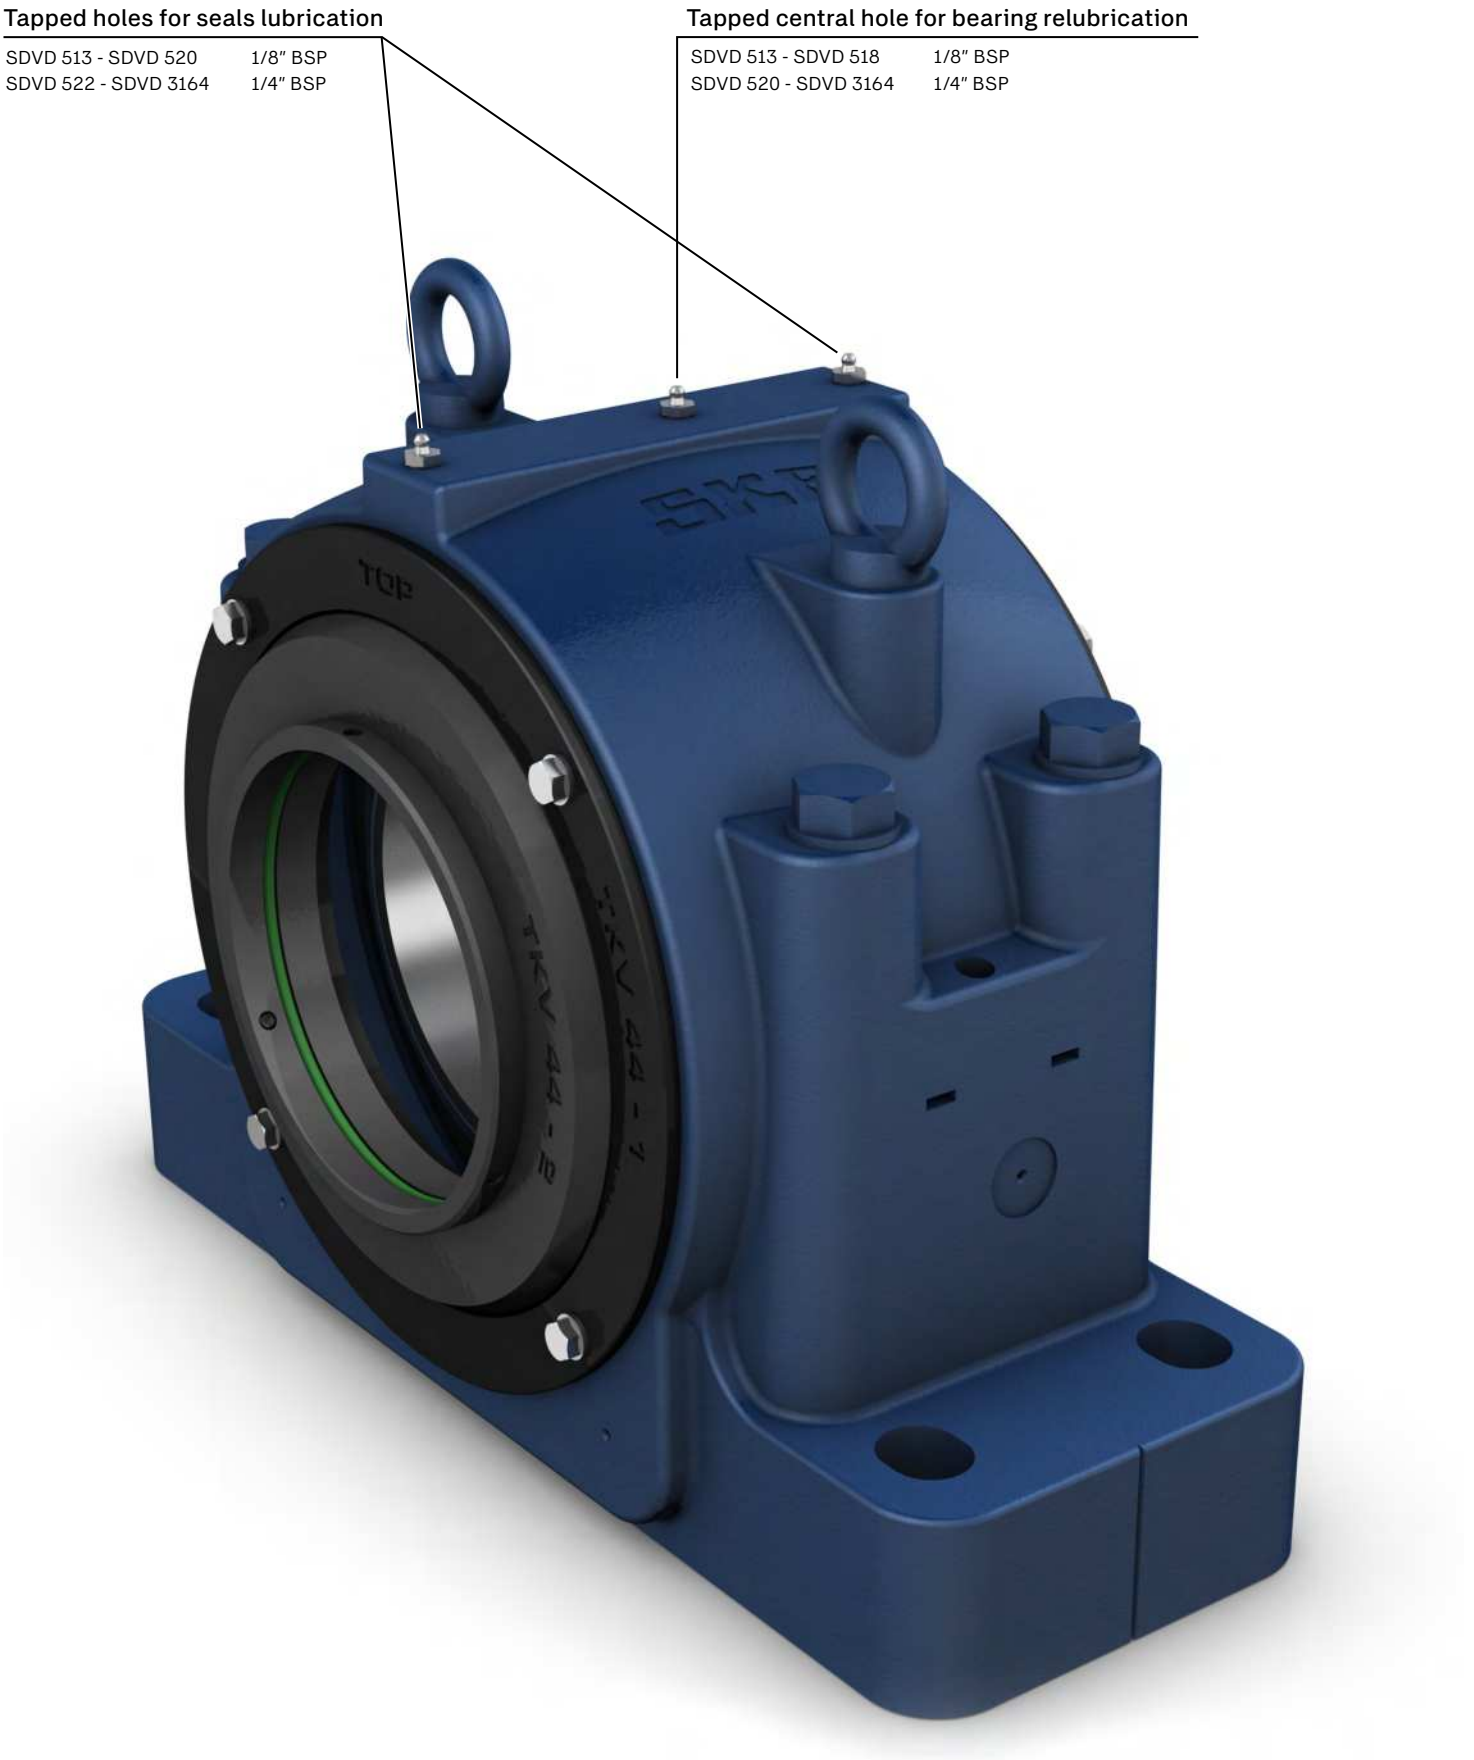

Figure 1: Lubrication locations for SDVD housings.

Associated components design considerations

Shaft

SDVD housings are designed for use with bearings fitted with SKF adapter sleeves. The sleeve seat on the shaft should meet tolerance class h9 or better. The radial runout should be within IT5/2 for tolerance for this class.

The seal counterfaces should be machined to tolerance class h9 or better, with cylindricity to grade IT5.

At the sleeve and seal positions, the shaft surface should have a roughness Ra ≤ 3.2 µm *(125 µin.)*.

Housing support surfaces

To maximize bearing service life and prevent deformation of the housing bore, SKF recommends that the flatness of the housing support surface is tolerance grade IT7 in accordance with ISO 1101. The surface should be finished to a roughness Ra ≤ 12.5 µm *(500 µin.)*.

Alignment

For optimum operation, for both the bearing and the seal, housing assemblies should be aligned. The tolerance for the alignment, using labyrinth seal clearances as an indicator, can be found in **table 7**.

The SDVD housing seals, TKV, include a bolt on the stationary component and rotating component.

1. The taconite seal rotating and stationary parts should be aligned. The outer flat surface of the stationary component should be in line with the corner of the rotating component as shown in **figure 2**. When the corner of the rotating labyrinth component is perfectly aligned with the face of the stationary component (carrier) around the entire circumference, then the bearing assembly is properly aligned. Tolerances in **table 7** for alignment are based on a target maximum misalignment of +/- 0.1 degrees in the bearing assembly. The seal's maximum allowable misalignment is 0.5 degrees.
2. The maximum total variation (Vx max) around the circumference of the axial offset distance 'X' should be no more than the values shown in table 7. For example, the maximum variation for SDVD 518 should be no more than 0.27 mm in the axial direction.
3. The nominal radial labyrinth gap is value 'Y' shown in **table 7**.
4. The maximum total variation (Vy max) around the circumference of the radial labyrinth gap 'Y' should be no more than the values shown in **table 7**.
5. For example, the maximum variation for SDVD 518 should be no more than 0.29 mm.

Condition monitoring attachment points

SDVD housings from size SDVD 522 and above are provided with pre-drilled locations suitable for attachment of vibration sensors.

All the relevant housing sizes have 2 radial (horizontal) and 2 axial positions provided.

Positions are drilled and tapped with 1/4″-28 UNF thread.

Vertical sensor locations, if required, can be drilled and tapped to suit individual requirements on site using the machined surface on top of the housing cap.

Note: Housing sizes from SDVD 513 to SDVD 520 do not have sufficient perpendicular areas to enable spotfacing and tapping. Sensors can be accommodated by gluing on pads, if required.

SDVD 5 series condition monitoring attachment points — Figure 3.1

SDVD 31 series condition monitoring attachment points — Figure 3.2

Ordering information

For SDVD housings, each of the following items must be ordered separately:

- housing
- seal kits (1 per housing for shaft end, 2 per housing for through shaft)
- end cover (1 per housing for shaft end)
- locating rings (2 per locating bearing)
- bearing
- adapter sleeve

Order example

Two plummer block housings with taconite seals are required for two 23138-2CS5K/VT143 sealed spherical roller bearings on H 3138 adapter sleeves. One housing will accommodate the non-locating bearing at the end of the shaft. The other housing will accommodate the locating bearing and a through shaft.

The following items should be ordered:

- 2 housings SDVD 3138
- 3 seal kits TKV 38 (each pack contains one seal assembly)
- 1 end cover ETV 330/305/4
- 2 locating rings FRB 10/320
- 2 bearings 23138-2CS5K/VT143
- 2 adapter sleeves OH 3138 H

Optional: 3 protective shrouds 1944715/38

Optional protective shrouds

In applications with extreme levels of contamination, customers might wish to add extra protection to further reduce the risk of fluids or dust entering the seal labyrinth. Such situations could typically include installations having frequent high-pressure cleaning or continuous impact by material cascading from above.

On request, SKF can supply protective shrouds which are simply installed over the seal assembly, using 2 of the seal carrier screws. The shrouds are constructed from sheet steel and powder-coated.

The shrouds can rotate +/- 90 degrees, so they will provide protection for housings in various orientations.

Shrouds can be installed from new, retrofitted, or existing applications in-situ. Overall dimensions of the housing assembly are not affected.

SDVD housing with shrouds — Figure 3

Lubrication guidelines for conveyors

[1] **Housing free space:**

For sealed bearings the housing should be filled to at least 80% of free space during assembly with grease.

For open bearings the housing should be filled to top 40% of free space during assembly with grease.

The grease should have a NLGI Grade 2 or 3 consistency.

[2] **Sealed bearings:**

If the bearing requires additional grease, apply the appropriate quantity of SKF LGEP 2 through the central lubrication groove.

Note:

- All grease supply values are approximate and may require adjustment depending on operating conditions, site experience and preferred lubrication procedures. Quantities are expressed as grams (g) but can also be read as cc (cm3) as the suggested values are approximate only and not based on precise calculations.
- The grease used in the housing should have good mechanical stability and water resistance.
- The initial bearing grease fill is SKF LGEP 2 for optimised bearing lubrication. Alternative suitable greases, if compatible with LGEP 2, may be selected depending on site maintenance practice requirements and lubrication system delivery requirements.
- The objective for housing seal grease supply is to have fresh grease in the seal at all times (just purging from the seal). The suggested grease supply amounts are indicative only and can be adjusted to meet the practical requirements depending on site conditions.
- The seal grease should be grade NLGI Grade 2 or 3 consistency, with good mechanical stability and water/washout resistance. The seal grease may be different from the bearing grease.

Sealed bearing regreasing schedule			Taconite seal regreasing schedule
